DATABASE MANAGEMENT SYSTEMS · ASSIGNMENT 7

Sample Data Insertion

Loading realistic, constraint-compliant data into every FoodExpress table

Project	FoodExpress – Online Food Delivery System	Submitted by	Dhruvan Karthik
DBMS	MySQL Community Server 8.0.46	GitHub	github.com/hidhruvan-prog
Database	`foodexpress`	Date	25 October 2026

1. Objective

Populate all nine tables of the `foodexpress` database with realistic sample data that simulates about eight weeks of operation of a food-delivery platform in four Indian cities, while satisfying every PRIMARY KEY, FOREIGN KEY, UNIQUE, CHECK and trigger rule defined in Assignments 5 and 6.

2. Design of the Sample Dataset

20 customers	**36** saved addresses	**10** restaurants	**52** menu items	**10** delivery agents
64 orders	**152** order lines	**64** payments	**34** reviews	**442** rows in total

- **Geography.** Customers, restaurants and riders are spread over Bengaluru, Mumbai, Hyderabad and Pune with real six-digit PIN codes. Every order is placed with a restaurant in the customer's own city and delivered by a rider from that city.
- **Menus.** Ten restaurants with different cuisines (Hyderabadi, South Indian, Chinese, Italian, street food, seafood, healthy, North Indian, desserts) and realistic rupee prices from ₹39 to ₹449.
- **Timeline.** Orders run from 1 September to 24 October 2026, mostly at lunch and dinner times. Five orders were placed on 24 October; four of them are still in progress (Placed, Preparing, Out for Delivery).
- **Order life cycle.** 52 orders are Delivered (each with a `delivered_at` time 24–58 minutes after ordering), 8 are Cancelled and 4 are in progress. Orders of ₹500 or more get free delivery; others pay ₹30–₹49.
- **Payments.** One payment per order; UPI is the most common method, followed by card, wallet and cash. Cancelled online payments are Refunded, cancelled cash orders are Failed, and cash for undelivered orders is Pending. Each amount equals the order's subtotal plus delivery fee.
- **Reviews.** About two-thirds of delivered orders (34 of 52) were reviewed, with a food rating, an optional rider rating and an optional comment.
- **Edge cases included on purpose** (used by the queries in Assignments 8–9): a newly registered customer with no orders, a newly onboarded restaurant (Sweet Tooth Desserts) with no orders, a new rider with no deliveries, two riders currently unavailable, two menu items marked unavailable, and an old, inactive address that is still referenced by earlier orders.
- **Privacy.** All names, phone numbers and e-mail addresses are fictitious (e-mails use the reserved `example.com` domain). Password hashes are SHA-256 hashes of throwaway demo strings.

3. Insertion Order

Because of the foreign keys, parent rows must exist before child rows. The script `sql/04_sample_data.sql` therefore inserts in this order, using multi-row `INSERT … VALUES` statements with explicit primary-key values so that the queries in later assignments refer to stable IDs.

Step	Table	Depends on	Rows
1	customers	–	20
2	addresses	customers	36
3	restaurants	–	10
4	menu_items	restaurants	52
5	delivery_agents	–	10
6	orders	customers, restaurants, addresses (composite), delivery_agents	64
7	order_items	orders, menu_items (+ same-restaurant trigger)	152
8	payments	orders	64
9	reviews	orders (+ delivered-only trigger)	34

4. Executing the Insert Script

Each INSERT below was executed on the server. To keep the report readable, only the first two rows of each statement are printed here; the complete statements are reproduced in the Appendix and in the repository. The `Records / Duplicates / Warnings` line is MySQL's own confirmation that every row was stored with no warnings.

5. Verifying the Loaded Data

5.1 Row counts

```sql
SELECT 'customers' AS table_name, COUNT(*) AS row_count FROM customers
UNION ALL SELECT 'addresses',       COUNT(*) FROM addresses
UNION ALL SELECT 'restaurants',     COUNT(*) FROM restaurants
UNION ALL SELECT 'menu_items',      COUNT(*) FROM menu_items
UNION ALL SELECT 'delivery_agents', COUNT(*) FROM delivery_agents
UNION ALL SELECT 'orders',          COUNT(*) FROM orders
UNION ALL SELECT 'order_items',     COUNT(*) FROM order_items
UNION ALL SELECT 'payments',        COUNT(*) FROM payments
UNION ALL SELECT 'reviews',         COUNT(*) FROM reviews;
```

```
mysql — foodexpress
mysql> SELECT 'customers' AS table_name, COUNT(*) AS row_count FROM customers
    -> UNION ALL SELECT 'addresses',       COUNT(*) FROM addresses
    -> UNION ALL SELECT 'restaurants',     COUNT(*) FROM restaurants
    -> UNION ALL SELECT 'menu_items',      COUNT(*) FROM menu_items
    -> UNION ALL SELECT 'delivery_agents', COUNT(*) FROM delivery_agents
    -> UNION ALL SELECT 'orders',          COUNT(*) FROM orders
    -> UNION ALL SELECT 'order_items',     COUNT(*) FROM order_items
    -> UNION ALL SELECT 'payments',        COUNT(*) FROM payments
    -> UNION ALL SELECT 'reviews',         COUNT(*) FROM reviews;
+-----------------+-----------+
| table_name      | row_count |
+-----------------+-----------+
| customers       |        20 |
| addresses       |        36 |
| restaurants     |        10 |
| menu_items      |        52 |

```

5.2 Consistency checks

Foreign keys already guarantee that no child row is orphaned. The query below checks the business rules that span tables; every count must be zero.

```sql
SELECT 'payment amount differs from order total' AS check_name, COUNT(*) AS violations
FROM payments p JOIN v_order_totals t ON t.order_id = p.order_id
WHERE p.amount <> t.total_amount
UNION ALL
SELECT 'order line priced differently from the menu', COUNT(*)
FROM order_items oi JOIN menu_items m ON m.item_id = oi.item_id
WHERE oi.price_at_order <> m.price
UNION ALL
SELECT 'order line from another restaurant', COUNT(*)
FROM order_items oi JOIN orders o ON o.order_id = oi.order_id
JOIN menu_items m ON m.item_id = oi.item_id
WHERE m.restaurant_id <> o.restaurant_id
UNION ALL
SELECT 'review of an undelivered order', COUNT(*)
FROM reviews r JOIN orders o ON o.order_id = r.order_id
WHERE o.order_status <> 'Delivered'
UNION ALL
SELECT 'restaurant in a different city from the address', COUNT(*)
FROM orders o JOIN restaurants re ON re.restaurant_id = o.restaurant_id
JOIN addresses a ON a.address_id = o.address_id
WHERE re.city <> a.city
UNION ALL
SELECT 'order without a payment', COUNT(*)
FROM orders o LEFT JOIN payments p ON p.order_id = o.order_id
WHERE p.payment_id IS NULL;
```

mysql — foodexpress

```
mysql> SELECT 'payment amount differs from order total' AS check_name, COUNT(*) AS violations
    -> FROM payments p JOIN v_order_totals t ON t.order_id = p.order_id
    -> WHERE p.amount <> t.total_amount
    -> UNION ALL
    -> SELECT 'order line priced differently from the menu', COUNT(*)
    -> FROM order_items oi JOIN menu_items m ON m.item_id = oi.item_id
    -> WHERE oi.price_at_order <> m.price
    -> UNION ALL
    -> SELECT 'order line from another restaurant', COUNT(*)
    -> FROM order_items oi JOIN orders o ON o.order_id = oi.order_id
    -> JOIN menu_items m ON m.item_id = oi.item_id
    -> WHERE m.restaurant_id <> o.restaurant_id

7. Conclusion

All 442 sample rows were inserted without errors or warnings, which shows that the data respects every key, CHECK constraint and trigger defined earlier. The dataset covers the whole order life cycle – from placement to delivery, cancellation, payment, refund and review – across four cities, and includes edge cases (unused restaurants, customers and riders; inactive addresses; unavailable dishes) so that the queries in Assignments 8 and 9 produce meaningful, non-trivial results.
